

Photo Description

The image shows a tall building with a big clock on it and an American flag waving in the wind. The clock has black hands that point to different numbers to tell time. Behind the building, you can see other tall buildings made of brick and glass.

Scientific Phenomena

The Anchoring Phenomenon is the American flag waving and moving in the wind. This happens because moving air (wind) pushes against the fabric of the flag, causing it to flutter and change shape. Wind is created when air moves from areas of high pressure to areas of low pressure, and this moving air has enough force to make lightweight objects like flags move and dance.

Core Science Concepts

1. Forces and Motion: Wind is a force that can push and pull objects, causing them to move in different directions.
2. Air as Matter: Even though we can't see air, it takes up space and has weight. When air moves, it can push against other objects.
3. Cause and Effect: The movement of air (cause) creates the effect of the flag waving and changing position.
4. Observable Properties: We can observe wind's effects on objects even though we cannot see the wind itself.

Pedagogical Tip:

Use a fan and lightweight materials like ribbons, tissue paper, or scarves to demonstrate how moving air creates forces that cause objects to move. This hands-on experience helps students connect the abstract concept of wind to concrete observations.

UDL Suggestions:

Provide multiple ways for students to experience wind effects: visual (watching flags wave), auditory (listening to wind sounds), and kinesthetic (feeling air from a fan on their skin). Consider students with mobility differences by bringing materials to them rather than requiring movement around the classroom.

Zoom In / Zoom Out

1. Zoom In: Air is made up of tiny particles called molecules that are constantly moving and bumping into each other. When these invisible particles move together in the same direction, they create wind that pushes against the flag's fabric fibers.
2. Zoom Out: This local wind is part of Earth's larger weather system, where air moves around the planet due to temperature differences between hot and cold areas, creating weather patterns that affect entire continents.

Discussion Questions

1. What evidence do you see that tells you wind is present in this picture? (Bloom's: Analyze | DOK: 2)
2. How might the flag look different on a day with no wind? (Bloom's: Apply | DOK: 2)
3. What other objects around our school might move the same way this flag moves? (Bloom's: Apply | DOK: 2)
4. If you wanted to test how strong the wind is, what materials could you use and why? (Bloom's: Create | DOK: 3)

Potential Student Misconceptions

1. Misconception: "Wind is made by trees moving their branches."
Clarification: Trees move because wind pushes them; trees don't create the wind.
2. Misconception: "Air isn't real because I can't see it."
Clarification: Air is matter that takes up space and has weight, even though it's invisible to our eyes.
3. Misconception: "The flag moves by itself."
Clarification: The flag needs a force (wind) to make it move; objects don't move without something pushing or pulling them.

NGSS Connections

- Performance Expectation: 3-PS2-1 Plan and conduct an investigation to provide evidence of the effects of balanced and unbalanced forces on the motion of an object.
- Disciplinary Core Idea: 3-PS2.A Forces and Motion - Each force acts on one particular object and has both strength and a direction.
- Crosscutting Concept: Cause and Effect - Simple tests can be designed to gather evidence to support or refute student ideas about causes.

Science Vocabulary

- * Force: A push or pull that can make objects move or change direction.
- * Wind: Moving air that can push against objects and make them move.
- * Motion: When something changes position or moves from one place to another.
- * Matter: Anything that takes up space and has weight, including air.
- * Pressure: The force that air or other things push with against surfaces.
