

## Photo Description

A fuzzy brown and black bee sits on a green leaf with white flower petals around it. The bee has striped patterns on its body and clear wings. You can see the bee's legs gripping the leaf as it rests between the flower petals.

## Scientific Phenomena

The anchoring phenomenon shown is pollination - the process where bees transfer pollen from one flower to another while collecting nectar for food. This happens because bees need energy-rich nectar to survive, and flowers need pollen moved to other flowers to reproduce. As the bee crawls into flowers to drink nectar, pollen grains stick to its fuzzy body and legs, then get brushed off when it visits the next flower. This creates a mutually beneficial relationship where both the bee and the plant get what they need to survive.

## Core Science Concepts

1. Animal Adaptations: Bees have special body parts that help them survive, including fuzzy hairs that collect pollen, long tongues to reach nectar, and strong wings for flying from flower to flower.
2. Plant Life Cycles: Flowers are the reproductive parts of plants that need pollen from other flowers to make seeds and grow new plants.
3. Interdependence: Bees and flowering plants depend on each other - bees get food (nectar) while plants get help reproducing through pollination.
4. Animal Behaviors: Bees have learned behaviors like communicating with other bees about where to find the best flowers through special dances.

### Pedagogical Tip:

Use hand motions and role-playing to help students understand the bee-flower relationship. Have some students be "bees" and others be "flowers" to act out pollination in a kinesthetic way.

### UDL Suggestions:

Provide visual supports like diagrams showing bee body parts, and offer multiple ways for students to demonstrate understanding through drawing, modeling with clay, or verbal explanations.

## Zoom In / Zoom Out

**Zoom In:** At the microscopic level, tiny pollen grains (like plant sperm cells) are sticking to the bee's branched hairs and being transferred to the female parts of flowers where they can fertilize eggs to create seeds.

Zoom Out: This bee is part of a larger ecosystem where pollinators help maintain food webs. Without bees and other pollinators, many plants couldn't reproduce, which would affect all the animals that eat those plants and the predators that eat those animals.

### Discussion Questions

1. What do you notice about the bee's body that might help it collect pollen? (Bloom's: Analyze | DOK: 2)
2. How do you think the relationship between bees and flowers helps both organisms survive? (Bloom's: Evaluate | DOK: 3)
3. What might happen to a garden if all the bees disappeared? (Bloom's: Predict/Apply | DOK: 2)
4. Why do you think flowers are often bright colors and smell sweet? (Bloom's: Analyze | DOK: 2)

### Potential Student Misconceptions

1. Misconception: Bees are trying to help plants on purpose.  
Clarification: Bees are actually just trying to get food for themselves - the pollination happens accidentally as they collect nectar.
2. Misconception: All bees make honey and live in hives.  
Clarification: Many bees are solitary and don't make honey - they just collect nectar and pollen for their own babies.
3. Misconception: Bees only visit one type of flower.  
Clarification: Most bees visit many different kinds of flowers, which helps them find food and helps plants get pollinated.

### NGSS Connections

Performance Expectation: 3-LS4-3 - Construct an argument that some animals form groups that help members survive.

Disciplinary Core Ideas:

- 3-LS4.D - Being part of a group helps animals obtain food, defend themselves, and cope with changes
- 3-LS1.B - Reproduction is essential to the continued existence of every kind of organism

Crosscutting Concepts:

- Cause and Effect - Students can observe how bee behavior causes pollination effects
- Systems and System Models - Bees and flowers work together as parts of an ecosystem

### Science Vocabulary

- \* Pollination: The process of moving pollen from one flower to another to help plants make seeds.
- \* Nectar: Sweet liquid inside flowers that bees drink for energy.
- \* Pollen: Tiny grains that flowers need to share with other flowers to make seeds.
- \* Adaptation: Special body parts or behaviors that help animals survive in their environment.
- \* Interdependence: When different living things need each other to survive.
