

## Photo Description

A large butterfly with black wings and cream-colored spots feeds on nectar from a bright pink flower with yellow center parts. The butterfly uses its long, thin tongue called a proboscis to reach deep inside the flower. This shows how butterflies and flowers work together in nature.

## Scientific Phenomena

This image demonstrates mutualistic pollination - a beneficial relationship between flowering plants and pollinators. The butterfly is attracted to the flower's bright colors and sweet nectar, which provides energy for flight and survival. As the butterfly feeds, pollen grains stick to its body and legs. When it visits the next flower, some pollen transfers to that flower's female parts, enabling plant reproduction. This co-evolutionary relationship has developed over millions of years, with flowers evolving specific colors, shapes, and rewards to attract their most effective pollinators.

## Core Science Concepts

1. **Pollination Process:** Animals like butterflies transfer pollen between flowers, helping plants reproduce and create seeds for the next generation.
2. **Interdependence:** Butterflies depend on flowers for food (nectar), while flowers depend on butterflies for reproduction through pollen transfer.
3. **Structural Adaptations:** The butterfly's proboscis is perfectly designed to reach nectar, while the flower's bright colors and sweet smell attract pollinators.
4. **Energy Transfer:** Nectar provides chemical energy that butterflies convert to mechanical energy for flying and metabolic processes.

### Pedagogical Tip:

Use hand gestures to help students remember the pollination process - have them "fly" their hands from flower to flower while explaining how pollen sticks and transfers. This kinesthetic approach helps cement the concept.

### UDL Suggestions:

Provide multiple ways for students to demonstrate understanding: drawing the pollination process, acting it out with props, or creating a digital presentation. This supports different learning preferences and abilities.

## Zoom In / Zoom Out

**Zoom In:** At the microscopic level, individual pollen grains contain male reproductive cells that must reach the female ovules inside flowers. Each pollen grain has a tough outer coating and specific proteins that help it stick to pollinator bodies and recognize compatible flowers.

**Zoom Out:** This pollination interaction is part of a larger ecosystem web where butterflies also serve as food for birds and spiders, while the plants they pollinate provide food and habitat for many other organisms. Global butterfly migration patterns help connect distant plant populations genetically.

### Discussion Questions

1. What might happen to the flowers if all the butterflies disappeared from this area? (Bloom's: Evaluate | DOK: 3)
2. How do you think the butterfly knows which flowers have the most nectar? (Bloom's: Analyze | DOK: 2)
3. Why do you think this flower is bright pink instead of green like its leaves? (Bloom's: Apply | DOK: 2)
4. What other animals might visit this same flower, and how might they be different from the butterfly? (Bloom's: Create | DOK: 3)

### Potential Student Misconceptions

1. Misconception: "Butterflies are trying to help flowers on purpose."  
Reality: Butterflies visit flowers only to get food for themselves; pollination happens accidentally as a beneficial side effect.
2. Misconception: "All insects pollinate flowers."  
Reality: Only certain insects are effective pollinators - many others may damage flowers or not transfer pollen between plants.
3. Misconception: "Flowers make nectar to be nice."  
Reality: Plants invest energy in making nectar specifically to attract pollinators that will help them reproduce.

### NGSS Connections

Performance Expectation: 5-LS2-1 - Develop a model to describe the movement of matter among plants, animals, decomposers, and the environment.

Disciplinary Core Ideas:

- 5-LS1.C - Organization for Matter and Energy Flow in Organisms
- 5-LS2.A - Interdependent Relationships in Ecosystems

Crosscutting Concepts:

- Systems and System Models
- Energy and Matter

### Science Vocabulary

- \* Pollination: The process of moving pollen from one flower to another to help plants make seeds.
- \* Proboscis: A long, tube-like tongue that butterflies use to suck nectar from flowers.
- \* Nectar: A sweet liquid that flowers make to attract animals like butterflies and bees.
- \* Interdependence: When two different living things need each other to survive and thrive.
- \* Adaptation: A special body part or behavior that helps an animal or plant survive in its environment.
