

## Photo Description

This large rock shows many layers stacked on top of each other like pancakes. The layers have different colors - some are brown, some are white, and some are tan. You can see how the rock formed over a very long time as different materials were pressed together to make these beautiful stripes.

## Scientific Phenomena

This image represents sedimentary rock formation as an anchoring phenomenon. The distinct layers (called strata) formed over millions of years as sediments like sand, mud, and organic materials were deposited in horizontal layers. Over time, pressure from overlying materials and chemical processes compressed and cemented these sediments into solid rock. The different colors and textures of each layer tell the story of different environmental conditions that existed when each layer was formed - some may represent ancient lake beds, river deposits, or ocean floors.

## Core Science Concepts

1. Layered Rock Formation: Sedimentary rocks form when particles settle in layers over long periods of time, with older layers at the bottom and newer layers at the top.
2. Geological Time Scale: The formation of these rock layers represents enormous amounts of time - much longer than human lifespans - showing how Earth changes very slowly.
3. Weathering and Erosion Evidence: The different materials in each layer came from weathering and erosion of other rocks and landscapes, then were transported and deposited in new locations.
4. Earth's History Record: Each layer acts like a page in Earth's history book, preserving information about past environments, climate, and life forms.

### Pedagogical Tip:

Have students create their own "sedimentary layers" using different colored sand or soil in clear containers. This hands-on model helps them visualize how layers form over time and why older layers are always at the bottom.

### UDL Suggestions:

Provide multiple ways for students to explore this concept: tactile learners can handle rock samples, visual learners can examine detailed photographs, and kinesthetic learners can act out the layering process by stacking different materials.

## Zoom In / Zoom Out

**Zoom In:** At the microscopic level, individual sediment particles (quartz grains, clay particles, fossil fragments) are cemented together by minerals like calcite or silica. Chemical reactions slowly bind these particles into solid rock through a process called lithification.

**Zoom Out:** This rock is part of Earth's larger rock cycle, where igneous, sedimentary, and metamorphic rocks continuously transform into each other. These sedimentary layers may have formed in ancient seas or river systems that covered this area millions of years ago, showing how Earth's surface has changed dramatically over geological time.

### Discussion Questions

1. What can we learn about the past by looking at the different layers in this rock? (Bloom's: Analyze | DOK: 3)
2. Why do you think some layers are thicker than others? (Bloom's: Evaluate | DOK: 2)
3. If you found a fossil in the bottom layer versus the top layer, which would be older and why? (Bloom's: Apply | DOK: 2)
4. How might this landscape have looked different millions of years ago when these layers were forming? (Bloom's: Create | DOK: 4)

### Potential Student Misconceptions

1. Misconception: "All rocks formed at the same time when Earth was made."

Clarification: Rocks form continuously over billions of years through different processes, and sedimentary rocks like this one formed much more recently than Earth itself.

2. Misconception: "The layers formed quickly, like when you stack blocks."

Clarification: Each layer took thousands to millions of years to form, requiring slow accumulation of sediments and gradual compression.

3. Misconception: "Rocks never change once they're formed."

Clarification: Rocks are constantly changing through weathering, erosion, and the rock cycle - this sedimentary rock will eventually break down or transform into other rock types.

### NGSS Connections

- Performance Expectation: 4-ESS1-1 - Identify evidence from patterns in rock formations and fossils in rock layers to support an explanation for changes in a landscape over time
- Disciplinary Core Ideas: 4-ESS1.C - Local, regional, and global patterns of rock formations reveal changes over time due to earth forces
- Crosscutting Concepts: Patterns - Patterns can be used as evidence to support an explanation
- Science and Engineering Practices: Analyzing and interpreting data from rock layer observations

### Science Vocabulary

- \* Sedimentary rock: Rock formed when layers of sediments are pressed together over long periods of time
- \* Strata: The individual layers visible in sedimentary rocks
- \* Erosion: The process of moving weathered rock and soil from one place to another
- \* Deposition: When eroded materials settle in a new location to form layers
- \* Geological time: The extremely long time periods over which Earth's rocks and landscapes form and change
