

## Photo Description

This bright yellow, bumpy organism is growing on dead leaves and wood on the forest floor. It has a spongy texture with many small holes and looks like it's spreading across the surface. This strange-looking yellow blob is actually a living thing called slime mold.

## Scientific Phenomena

The anchoring phenomenon shown here is slime mold growth and feeding behavior. This organism (*Physarum polycephalum* or similar species) is in its plasmodium stage, where it actively moves and feeds on decaying organic matter. The bright yellow color indicates it's healthy and actively consuming bacteria, fungi, and decomposing plant material. Slime molds are unique because they can move without muscles, change shape, and solve simple problems like finding the shortest path to food sources. They represent a fascinating example of how living things can be very different from plants and animals while still carrying out essential life processes.

## Core Science Concepts

1. Living vs. Non-living Characteristics: Slime molds demonstrate that living things can look very different from familiar plants and animals, yet still grow, move, respond to environment, and need food and water.
2. Decomposition and Nutrient Cycling: These organisms play a crucial role in breaking down dead plant material, returning nutrients to the soil for new plants to use.
3. Adaptation to Environment: The bright yellow color and spreading growth pattern help slime molds find food efficiently in their forest habitat.
4. Life Cycles and Growth: Slime molds go through different stages of life, changing their appearance and behavior as they grow and reproduce.

### Pedagogical Tip:

Use this image to challenge students' preconceptions about what "counts" as a living thing. Have them apply the characteristics of living things checklist to determine if this mysterious organism is alive, encouraging scientific reasoning skills.

### UDL Suggestions:

Provide multiple ways for students to explore this concept: tactile models made from play dough, time-lapse videos showing movement, and hands-on observations of safe decomposing materials in your schoolyard to accommodate different learning preferences and abilities.

## Zoom In / Zoom Out

**Zoom In:** At the microscopic level, slime molds are made of a single giant cell with thousands of nuclei that can coordinate movement and decision-making without a brain or nervous system. The cytoplasm flows like a slow river, carrying nutrients and information throughout the organism.

**Zoom Out:** In the forest ecosystem, slime molds are essential decomposers that work alongside bacteria, fungi, and insects to break down dead plant material, creating rich soil that supports new plant growth and maintains the health of the entire woodland community.

## Discussion Questions

1. What evidence can you find in this photo that shows this organism is alive? (Bloom's: Analyze | DOK: 2)
2. How might this yellow organism help other living things in the forest? (Bloom's: Evaluate | DOK: 3)
3. What do you think would happen to this slime mold if all the dead leaves were removed? (Bloom's: Predict | DOK: 2)
4. Why do you think this organism is bright yellow instead of green like most plants? (Bloom's: Analyze | DOK: 2)

## Potential Student Misconceptions

1. Misconception: "It's not alive because it doesn't look like plants or animals."  
Clarification: Living things come in many forms. This organism grows, moves, eats, and reproduces, making it definitely alive.
2. Misconception: "It's a plant because it's growing on the ground."  
Clarification: Unlike plants, slime molds cannot make their own food from sunlight. They must eat other organisms to survive.
3. Misconception: "It's dangerous or yucky because it's slimy and weird-looking."  
Clarification: Most slime molds are harmless and actually help keep forests healthy by cleaning up dead materials.

## NGSS Connections

Performance Expectation: 3-LS1-1 - Develop models to describe that organisms have unique and diverse life cycles but all have in common birth, growth, reproduction, and death.

Disciplinary Core Ideas:

- 3-LS1.B - Growth and Development of Organisms
- 3-LS4.C - Adaptation

Crosscutting Concepts:

- Patterns
- Structure and Function

## Science Vocabulary

- \* Organism: Any individual living thing that can grow and reproduce.
- \* Decomposer: A living thing that breaks down dead plants and animals.
- \* Plasmodium: The active, moving stage of a slime mold's life cycle.

- \* Habitat: The natural place where an organism lives and finds what it needs to survive.
- \* Nutrient: A substance that living things need to grow and stay healthy.
