

## Photo Description

This picture shows the inside of a car engine with its hood open. You can see many metal parts, tubes, and wires that work together to make the car move. The engine has different sections that help turn gasoline into power for the car.

## Scientific Phenomena

The anchoring phenomenon here is energy transformation - specifically how chemical energy stored in gasoline is converted into mechanical energy (motion) through combustion. Inside the engine, fuel mixes with air and burns in controlled explosions within cylinders. This burning creates hot gases that expand rapidly, pushing pistons that ultimately turn the car's wheels. This demonstrates the fundamental principle that energy cannot be created or destroyed, only changed from one form to another.

## Core Science Concepts

1. Energy Transformation: Chemical energy in fuel changes to heat energy through burning, then to mechanical energy for movement
2. Simple Machines: The engine contains levers, pulleys, and other simple machines working together as a complex machine
3. Force and Motion: Burning fuel creates forces that push engine parts, which transfer motion to the wheels
4. Matter and Its Properties: Liquids (fuel, oil) and gases (air, exhaust) have different properties that help the engine work

### Pedagogical Tip:

Use the 5E instructional model when teaching about engines: Engage students by asking what makes cars move, Explore by examining toy cars or simple machines, Explain energy transformation concepts, Elaborate by connecting to other machines they know, and Evaluate through hands-on activities.

### UDL Suggestions:

Provide multiple ways to represent this concept: use physical models of pistons in cylinders, create simple drawings showing energy flow, and allow kinesthetic learners to act out the piston movements with their arms to understand the mechanical motion.

## Zoom In / Zoom Out

1. Zoom In: At the molecular level, fuel molecules are breaking apart and combining with oxygen molecules during combustion, releasing stored chemical bonds as heat and light energy that wasn't visible before.
2. Zoom Out: This car engine is part of a larger transportation system that moves people and goods around the world, and the burning of fossil fuels in millions of engines affects Earth's atmosphere and climate patterns globally.

## Discussion Questions

1. What do you think happens to the gasoline after it goes into the engine? (Bloom's: Analyze | DOK: 2)
2. How is a car engine similar to other machines you use every day? (Bloom's: Apply | DOK: 2)
3. Why do you think car engines need so many different parts working together? (Bloom's: Evaluate | DOK: 3)
4. What would happen if we put water instead of gasoline in the engine? (Bloom's: Predict | DOK: 2)

## Potential Student Misconceptions

1. Misconception: "The engine creates energy from nothing"

Clarification: Engines transform energy from fuel into motion - they don't create new energy, just change it from one form to another.

2. Misconception: "Only the gas pedal makes the car go"

Clarification: Many systems work together including the engine, transmission, and wheels - the gas pedal just controls how much fuel enters the engine.

3. Misconception: "All the fuel turns into motion"

Clarification: Most energy from fuel becomes waste heat - only about 25% actually moves the car forward.

## NGSS Connections

- Performance Expectation: 5-PS1-3 (Make observations and measurements to identify materials based on their properties)
- can be adapted down for 3rd grade observations
- Disciplinary Core Ideas: PS3.B (Conservation of Energy and Energy Transfer), PS3.C (Relationship Between Energy and Forces), ETS1.A (Defining and Delimiting Engineering Problems)
- Crosscutting Concepts: Energy and Matter, Systems and System Models, Cause and Effect

## Science Vocabulary

- \* Engine: A machine that burns fuel to create power for movement
- \* Fuel: A substance like gasoline that stores energy and can be burned
- \* Combustion: The process of burning something with oxygen to release energy
- \* Piston: A moving part inside the engine that goes up and down to create power
- \* Energy transformation: When energy changes from one type to another type
