

## Photo Description

This rock shows many layers stacked on top of each other like pages in a book. The layers have different colors - some are brown, white, and tan. You can see the rock sitting on a blue wooden pallet with small rocks all around it.

## Scientific Phenomena

The Anchoring Phenomenon this image represents is sedimentary rock formation through layering. This rock formed over millions of years as sediments (tiny pieces of sand, mud, and other materials) were deposited in layers at the bottom of ancient seas, lakes, or rivers. Each layer represents a different time period when different materials settled. Over time, the weight of upper layers pressed down on lower layers, cementing them together into solid rock through a process called lithification.

## Core Science Concepts

1. Sedimentary Rock Formation: Rocks can form when layers of sediment are pressed together over long periods of time
2. Geological Time: Rock layers show us that Earth's history spans millions and billions of years
3. Stratification: Different colored layers represent different materials that were deposited at different times
4. Weathering and Erosion: The materials in this rock came from other rocks that were broken down and moved by water, wind, or ice

### Pedagogical Tip:

Use a clear container and different colored sand or soil to demonstrate how layers form over time. Have students add one layer at a time and press gently to show how sedimentary rocks develop.

### UDL Suggestions:

Provide tactile experiences by letting students handle different sediment samples (sand, clay, small pebbles) and create their own layered models using clear containers. This supports kinesthetic learners and makes abstract geological time concepts more concrete.

## Zoom In / Zoom Out

1. Zoom In: At the microscopic level, individual sediment grains are cemented together by minerals that act like natural glue, binding sand, silt, and clay particles into solid rock
2. Zoom Out: This rock is part of Earth's rock cycle, where all rocks are constantly being formed, broken down, and reformed through processes happening across entire continents and ocean basins

## Discussion Questions

1. What do you think each layer in this rock tells us about the past? (Bloom's: Analyze | DOK: 3)
2. How do you think this rock would be different if it formed in a desert versus underwater? (Bloom's: Evaluate | DOK: 3)
3. What evidence do you see that this rock formed in layers over time? (Bloom's: Apply | DOK: 2)
4. If you found this rock, what questions would you want to ask about Earth's history? (Bloom's: Create | DOK: 2)

## Potential Student Misconceptions

1. Misconception: "All rocks are the same age as Earth"  
Clarification: Rocks form at different times - some are very old, others are still forming today
2. Misconception: "Rock layers formed quickly"  
Clarification: Most sedimentary rock layers took thousands to millions of years to form
3. Misconception: "Rocks don't change"  
Clarification: Rocks are constantly changing through weathering, erosion, and reformation

## NGSS Connections

- Performance Expectation: 2-ESS1-1 (Use information from several sources to provide evidence that Earth events can occur quickly or slowly)
- Disciplinary Core Idea: 2-ESS1.C - The History of Planet Earth
- Crosscutting Concept: Patterns - Patterns in the natural world can be observed

## Science Vocabulary

- \* Sediment: Small pieces of rock, sand, and mud that settle in layers
- \* Layers: Flat sections stacked on top of each other like pancakes
- \* Sedimentary rock: Rock made from sediments pressed together over time
- \* Fossil: Remains of ancient plants or animals found in rocks
- \* Erosion: When wind, water, or ice moves rocks and soil to new places
